ABSTRACT

A method and system for enabling a callback from an entity to an equipment initiating a session wherein nodes involved in handling the session, are adapted to store information for the session, preferably for a predetermined time from the beginning of the session. The information includes an address of at least one other node in the signaling path, and may also include an identity of the equipment. The at least one other node will be used, in case of callback, to carry signaling related to the callback from the entity to the equipment. Preferably, signaling bearer for establishing the session is maintained for a certain time from the beginning of the signaling bearer activation. The nodes preferably are IMS nodes and include P-CSCF, S-CSCF, or MGCF node.
